

(a) the same arithmetic, three names

neutral

pen=1 + cup, cup=2 + 3; pen=?

the name agrees

pen=1 + five, five=2 + 3; pen=?

five really is 5

the name lies

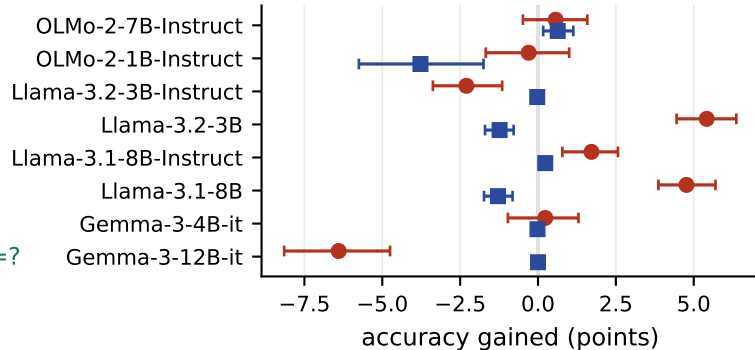

pen=1 + two, two=2 + 3; pen=?

two is really 5

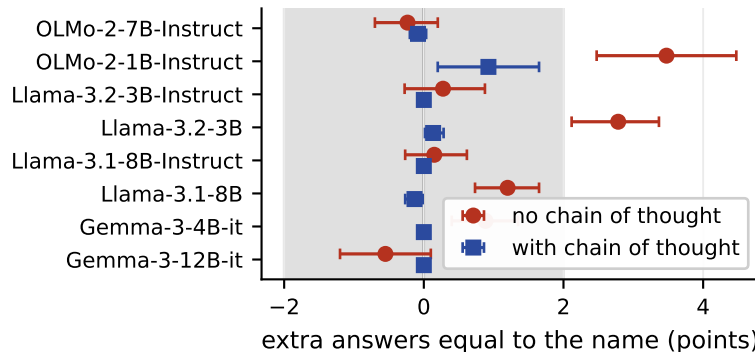

The answer is 6 in all three.

The model either writes the steps
"cup=2 + 3, cup=5, pen=1 + cup,
pen=1 + 5, pen=6",
or answers "pen=6" directly.

(b) when the name agrees, does it help?

when the name lies, is it answered?

(c) what the model holds, token by token
